

Metastatic-site immune decoupling module

Interpretation: GSE272362 supports a metastatic-site contrast in which primary tumors and liver metastases preserve CAF-core-centered immune and tumor-aggressive organization, whereas lymph-node metastases retain stromal-tumor coupling but selectively weaken immune/IFN coupling to the CAF core.

Boundary: the LN finding is a biologically sharp spatial contrast from five LN metastasis samples and should be framed as a metastatic immune-remodeling lead, not as a clinical subtype or causal mechanism.
